## One-sided alternative hypotheses

For "one-sided alternative hypotheses" just calculate posterior probabilities.

For example, with hypotheses

$$H_0: \theta \le \theta_0$$
 versus  $H_A: \theta > \theta_0$ 

Calculate

$$p(H_0|y) = P(\theta \le \theta_0|y)$$

and

$$p(H_A|y) = P(\theta > \theta_0|y).$$

#### Posterior probabilities

Let  $Y \sim Bin(n, \theta)$  with hypotheses

$$H_0: \theta \leq 0.5$$
 and  $H_A: \theta > 0.5$ .

Assume  $\theta \sim Unif(0,1)$  and obtain the posterior i.e.

 $\theta|y \sim Be(1+y, 1+n-y).$ 

Then calculate

$$p(H_0|y) = P(\theta \le 0.5|y) = 1 - p(H_A|y).$$

```
n = 10
y = 3
probH0 = pbeta(0.5, 1+y, 1+n-y)
probH0 # p(H_0/y)
```

[1] 0.8867188

1=probHO # m(H A/m)

# Posterior model probabilities

Calculate the posterior model probabilities over some set of J models i.e,

$$p(M_j|y) = \frac{p(y|M_j)p(M_j)}{p(y)} = \frac{p(y|M_j)p(M_j)}{\sum_{k=1}^J p(y|M_k)p(M_k)}.$$

In order to accomplish this, we need to determine

• prior model probabilities:

$$p(M_j)$$
 for all  $j = 1, \ldots, J$ 

and

• priors over parameters in each model:

$$p(y|M_j) = \int p(y|\theta) p(\theta|M_j) d\theta.$$
TAT5870@ISU) I07 - Posterior model

## Prior predictive distribution

The prior predictive distribution for model  $M_j$  is

$$p(y|M_j) = \int p(y|\theta)p(\theta|M_j)d\theta.$$

For example, let

 $y|\mu, M_j \sim N(\mu, 1)$ 

and

$$\mu|M_j \sim N(0, C),$$

then

$$y|M_j \sim N(0, 1+C).$$

## Bayes Factor

In the context of a null hypothesis  $(H_0)$  and an alternative hypothesis  $(H_A)$  we have

$$p(H_0|y) = \frac{p(y|H_0)p(H_0)}{p(y|H_0)p(H_0) + p(y|H_A)p(H_A)}$$
$$= \left[1 + \frac{p(y|H_A)}{p(y|H_0)} \frac{p(H_A)}{p(H_0)}\right]^{-1}$$
$$= \left[1 + BF(H_A:H_0)\frac{p(H_A)}{p(H_0)}\right]^{-1}$$

where

$$BF(H_A:H_0) = \frac{p(y|H_A)}{p(y|H_0)}$$

is the Bayes Factor for  $H_A$  over  $H_0$ .

#### Normal model

```
Let Y \sim N(\mu, 1) and H_0: \mu = 0 vs H_A: \mu \neq 0.
Assume p(H_0) = p(H_A) and \mu | H_A \sim N(0, 1),
then
\begin{aligned} y | H_0 &\sim N(0, 1) \\ y | H_A &\sim N(0, 2). \end{aligned}
```

```
y = 0.3
probH0 = 1/(1+dnorm(y, 0, sqrt(2))/dnorm(y, 0, 1))
probH0 # p(H_0/y)
[1] 0.5803167
1-probH0 # p(H_A/y)
[1] 0.4196833
```

#### Ratio of predictive densities

### Normal model

November 22, 2024

### Prior impact

Let  $Y \sim N(\mu, 1)$  and  $H_0: \mu = 0$  vs  $H_A: \mu \neq 0$ . Assume  $p(H_0) = p(H_A)$  and  $\mu | H_A \sim N(0, C)$ , then  $y | H_0 \sim N(0, 1)$ 

and

$$p(H_0|y) = \left[1 + \frac{p(y|H_A)}{p(y|H_0)}\right]^{-1}.$$

## Prior impact

#### Interpretation

Since posterior model probabilities depend on the prior predictive distribution

$$p(y|M_j) = \int p(y|\theta)p(\theta|M_j)d\theta$$

posterior model probabilities tell you which model does a better job of prediction and priors,  $p(\theta|M_i)$ , must be informative.

#### Do pvalues and posterior probabilities agree?

Suppose  $Y \sim Bin(n, \theta)$  and we have the hypotheses  $H_0: \theta = 0.5$  and  $H_A: \theta \neq 0.5$  We observe n = 10,000 and y = 4,900 and find the *p*-values

p-value  $\approx 2P(Y \le 4900) = 0.0466$ 

so we would reject  $H_0$  at the 0.05 level.

If we assume  $p(H_0) = p(H_A) = 0.5$  and  $\theta | H_A \sim Unif(0, 1)$ , then the posterior probability of  $H_0$ , is

$$p(H_0|y) \approx \frac{1}{1+1/10.8} = 0.96,$$

so the probability of  $H_0$  being true is 96%.

It appears the posterior probability of  ${\cal H}_0$  and  $p\mbox{-value}$  completely disagree!

(STAT5870@ISU)

### Jeffreys-Lindley Paradox

The Jeffreys-Lindley Paradox concerns a situation when comparing two hypotheses  $H_0$  and  $H_1$  given data y and find

- a frequentist test result is significant leading to rejection of  $H_0$ , but
- the posterior probability of  $H_0$  is high.

#### This can happen when

- the effect size is small,
- n is large,
- $H_0$  is relatively precise,
- $H_1$  is relative diffuse, and
- the prior model odds is  $\approx 1$ .

#### No real paradox

p-values:

- $\bullet\,$  a  $p\mbox{-value}$  measure how incompatible your data are with the null hypothesis, but
- it says nothing about how incompatible your data are with the alternative hypothesis.

Posterior model probabilities are

- a measure of the (prior) predictive ability of a model relative to the other models, but
- this requires you to have at least two (or more) well-thought out models with informative priors.

Thus, these two statistics provide completely different measures of model adequecy.

# Summary

- Use posterior probabilities for one-sided alternative hypotheses.
- Posterior model probabilities evaluate relative predictive ability.
